CHOW STABILITY OF CURVES OF GENUS 4 IN $\mathbb{P}^3$

HOSUNG KIM

Abstract. In the paper, we study the GIT construction of the moduli space of Chow semistable curves of genus 4 in $\mathbb{P}^3$. By using the GIT method developed by Mumford and a deformation theoretic argument, we give a modular description of this moduli space. We classify Chow stable or Chow semistable curves when they are irreducible or nonreduced. Then we work out the case when a curve has two components. Our classification provides some clues to understand the birational map from the moduli space $\overline{M}_4$ of stable curves of genus 4 to the moduli space of Chow semistable curves of genus 4 in $\mathbb{P}^3$.

1. Introduction

An n-canonical curve $C \subset \mathbb{P}^N$ is a stable curve embedded by $|\omega_C^{\otimes n}|$. Let $\mathrm{Chow}_{g,n}$ be the closure of the locus of n-canonical curves of genus g in the Chow variety. Then we have the following GIT quotient:

$$\mathrm{Chow}_{g,n}//\mathrm{SL_{N+1}}$$

where $N = (2n-1)(g-1)-1$ if $g \geq 2$ and $N = g-1$ if $n = 1$. To understand this GIT quotient space, we need to have a criterion for the GIT stability of a Chow form, i.e., Chow stability. In [9], Lee and the author provided a criterion for the stability of plane curves in terms of log canonical thresholds. This criterion implies that $(\mathbb{P}^2, C)$ should be replaced in Hacking's construction of a compact moduli space of plane curves [2] if C is not Chow stable.

Mumford [11] showed that, for $n \geq 5$ and $g \geq 2$, the Chow stable points are precisely the n-canonical curves. Schubert [12] considered the case $n = 3$ and $g \geq 3$. He proved that a tri-canonical curve is stable if and only if it is pseudo-stable and also showed that there is no strictly Chow semistable curve. Hyeon and Lee considered the case $n = 3, 4$ and $g = 2$. In [7], they proved that genus two pseudo-stable curve are indeed Chow semistable and completely classified the strictly Chow semistable points. They also concerned the case $n = 2$ and $g = 3$. In [8], they showed that the quotient space is the moduli space of c-stable curves. Hassett and Hyeon studied for the case $n = 2$ and $g \geq 4$ in [5] and for the case $n = 4$ in [6]. However, at present we have little understanding of $\mathrm{Chow_{g,1}}//\mathrm{SL_{N+1}}$ for $g \geq 4$.

This work is a large part of the author's Ph.D. thesis submitted to Sogang University in 2007 written under Yongnam Lee. The author wishes to thank him for his guidance and patience. Also the author thanks Brendan Hassett for valuable comments. The author was supported by the Korea Science and Engineering Foundation (KOSEF) grant funded by the Korea government (MOST) (No. R01-2007-000-10948-0).

This paper concerns the case $n = 1$ and $g = 4$. To determine which curve is Chow stable or Chow semistable, we use a classical method developed by Mumford and a deformation theoretic argument. Precisely we have the following results:

Theorem 1.1. (1) *Let C be a smooth curve of genus 4. If C is a nonhyperelliptic curve, then $C \subset \mathbb{P}^3$ embedded by $|\omega_C|$ is Chow stable. If C is a hyperelliptic curve, then the canonical image of C, i.e. a double curve supported on a twisted cubic curve in $\mathbb{P}^3$, is strictly Chow semistable. Furthermore, it is the only nonreduced Chow semistable curve representing a point in* $\mathrm{Chow}_{4,1}//\mathrm{SL}_4$.

(2) *Let C be a reduced, irreducible and nondegenerate curve of genus 4 and degree 6 in $\mathbb{P}^3$. Assume that C has at most nodes, ordinary cusps and tacnodes as its singularities. Then C is Chow semistable. Moreover C is strictly Chow semistable if and only if C has a tacnode and there is a hyperplane H meeting with multiplicity 3 at each inverse point of the tacnode in $\tilde{C}$ where $\tilde{C}$ is the normalizaion of C.*

(3) *All three connected stable curves of genus 4 with two smooth components except 3-pointed elliptic tails are Chow stable. All 3-pointed elliptic tails are strictly Chow semistable and are identified in* $\mathrm{Chow}_{4,1}//\mathrm{SL}_4$.

Theorem will be proved in Section 3.

According to the above results, we have a birational map

$$\overline{M}_4 \dashrightarrow \mathrm{Chow}_{4,1}//\mathrm{SL}_4$$

and some clues to understand this birational map. We know that an elliptic tail in a stable curve of genus 4 is replaced by a curve with a cusp by (2). We show that stable curves of genus 4 in the boundary divisor δ_2 are identified in $\mathrm{Chow}_{4,1}//\mathrm{SL}_4$. An elliptic bridge in a stable curve of genus 4 is replaced by a curve with a tacnode.

Throughout, we work over an algebraically closed field k of characteristic zero. The genus of a curve means its arithmetic genus. For a smooth point $p \in C$, we use the notation $\mathcal{I}(C)_{p\times\{0\}} = (t^{r_0}s^{v_0}, t^{r_1}s^{v_1}, t^{r_2}s^{v_2}, t^{r_3}s^{v_3})$ for the ideal of $\mathcal{O}_{C\times\mathbb{A}^1, p\times\{0\}}$ generated by $t^{r_0}s^{v_0}$,..., $t^{r_3}s^{v_3}$ where s (resp. t) is the local parameter of $\mathcal{O}_{C,p}$ (resp. $\mathcal{O}_{\mathbb{A}^1,0}$), $v_i = v(X_i)$ where v is the natural valuation on $\mathcal{O}_{C,p}$ and X_0,...,X_3 are the given homogeneous coordinates of $\mathbb{P}^3$.

2. CHOW STABILITY

In this section, we will review some methods for determining which Chow cycles are stable or semistable developed by Mumford, Gieseker and Schubert. For more detail, we refer to [11] and [12].

A weighted flag F of $H^0(\mathbb{P}^n, \mathcal{O}_{\mathbb{P}^n}(1))$ is a filtration $H^0(\mathbb{P}^n, \mathcal{O}_{\mathbb{P}^n}(1)) = V_0 \supset \cdots \supset V_n$ where each V_i is a vector space of dimension $n+1-i$ and a set of integers $r_0 \geq \cdots \geq r_n \geq 0$. Note that, for coordinates X_0,...,X_n on $\mathbb{P}^n$, we have a filtration $H^0(\mathbb{P}^n, \mathcal{O}_{\mathbb{P}^n}(1)) = V_0 \supset \cdots \supset V_n$ where each $V_i = \mathrm{span}\{X_i, ..., X_n\}$.

Let X be a variety in $\mathbb{P}^n$ of dimension r, and let F be a weighted flag of $H^0(\mathbb{P}^n, \mathcal{O}_{\mathbb{P}^n}(1))$ as above. Let $\alpha : \tilde{X} \to X$ be a proper birational morphism of varieties. Let $\mathcal{I}(X) = \mathcal{I}$ be the ideal sheaf of $\mathcal{O}_{\tilde{X}\times\mathbb{A}^1}$ defined by

$$\mathcal{I} \cdot [\alpha^*\mathcal{O}_X(1) \otimes \mathcal{O}_{\mathbb{A}^1}] = \text{ the subsheaf generated by } t^{r_i}\alpha^*X_i \ (i = 1, ..., n).$$

We denote

$$e_F(X) := \text{ n.l.c. of } \chi(\mathcal{O}_{\tilde{X}\times\mathbb{A}^1}(m)/\mathcal{I}^m\mathcal{O}_{\tilde{X}\times\mathbb{A}^1}(m))$$

where $\chi(\mathcal{O}_{X'}(m)/\mathcal{I}^m\mathcal{O}_{X'}(m))$ is a polynomial of degree $r+1$ for $m \gg 0$. By Lemma 5.6 of [11], we know that $e_F(X)$ is independent of α.

For a Chow cycle $X = \sum a_i Y_i$ where Y_i are varieties, we let $e_F(X) := \sum a_i e_F(Y_i)$.

Theorem 2.1. [11] *A Chow cycle X is Chow semistable (resp. Chow stable) if and only if*

$$e_F(X) - \frac{r+1}{n+1} \deg X \sum r_i \leq 0 \quad (\textit{resp. } < 0)$$

for every weighted flag F of $H^0(\mathbb{P}^n, \mathcal{O}_{\mathbb{P}^n}(1))$.

We now consider ways to estimate $e_F(X)$.

Lemma 2.2. [12] *Let X be a r dimensional subvariety of $\mathbb{P}^n$. Let F be the weighted flag determined by x_0,...,x_n and $r_0 \geq ... \geq r_n = 0$. Suppose x_j,...,x_n vanish on X and $r_0 = \cdots = r_{j-1}$. Then $e_F(X) = (r+1)r_0 \deg(X)$.*

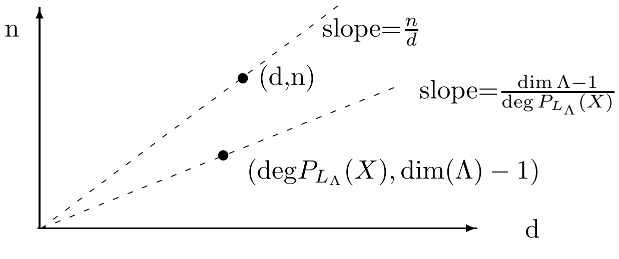
Lemma 2.3. [12] *Let R be the homogeneous coordinate ring of a variety X in $\mathbb{P}^n$. Let I_X be the ideal in $R[t]$ generated by $\{X_i t^{r_i} | i = 0, ..., n\}$. Then $e_F(X) =$ n.l.c. $\dim_k(R[t]/I_X^m)_m$ where $R[t] = \oplus_{i=1}^{\infty} R_i[t]$ is the grading for $R[t]$.*

In the rest of this section, we assume that X is a subvariety of $\mathbb{P}^n$ of dimension 1 and F is a weighted flag of $H^0(\mathbb{P}^n, \mathcal{O}_{\mathbb{P}^n}(1))$ as above.

Let $\alpha : \tilde{X} \to X$ be the normalization of X. Suppose there is an i such that $\alpha^* X_i$ does not vanish on $\tilde{X}$ and $r_i = 0$. For each $p \in \tilde{X}$, we denote $e_F(\tilde{X})_p =$ n.l.c. $\dim_k(\mathcal{O}_{\tilde{X}\times\mathbb{A}^1, p\times\{0\}}/\mathcal{I}^m_{p\times\{0\}})$. Then $e_F(X) = \sum_{p\in\tilde{X}} e_F(\tilde{X})_p$. By assumption, we know that $e_F(\tilde{X})_p = 0$ for all but finitely many points $p \in \tilde{X}$.

Lemma 2.4. [12] *In the above situation, suppose $v(\alpha^* X_i) + r_i \geq a$ for $i = 0, ..., n$ where v is the natural valuation on $\mathcal{O}_{\tilde{X},p}$. Then $e_F(\tilde{X})_p \geq a^2$.*

For a subvector space Λ of $H^0(\mathbb{P}^n, \mathcal{O}_{\mathbb{P}^n}(1))$, let L_Λ be the linear space defined by sections in Λ. Let $P_{L_\Lambda} : \mathbb{P}^n - L_\Lambda \to \mathbb{P}(\Lambda)$ be the projection with center L_Λ. By composition of P_{L_Λ} and the normalization $\tilde{X} \to X$, we get a morphism $\alpha_{L_\Lambda} : \tilde{X} \to \mathbb{P}(\Lambda)$. Let $\deg P_{L_\Lambda}(X)$ be the degree of the image of α_{L_Λ} multiplied by the degree of α_{L_Λ} if $\dim(\alpha_{L_\Lambda}(C)) = 1$ and 0 otherwise. Let d be the degree of X. We say X is linearly semistable (resp. stable) if the slop of the line joining $(0,0)$ and $(\deg P_{L_\Lambda}(X), \dim(\Lambda) - 1)$ is smaller than or equal to (resp. strictly smaller than) that of the line joining $(0,0)$ and (d, n) for all $\Lambda \subset H^0(\mathbb{P}^n, \mathcal{O}_{\mathbb{P}^n}(1))$ such that $\dim \alpha_{L_\Lambda}(X) = 1$.



n
slope=$\frac{n}{d}$
(d,n)
slope=$\frac{\dim\Lambda-1}{\deg P_{L_\Lambda}(X)}$
$(\deg P_{L_\Lambda}(X), \dim(\Lambda)-1)$
d

Mumford showed the following in [11].

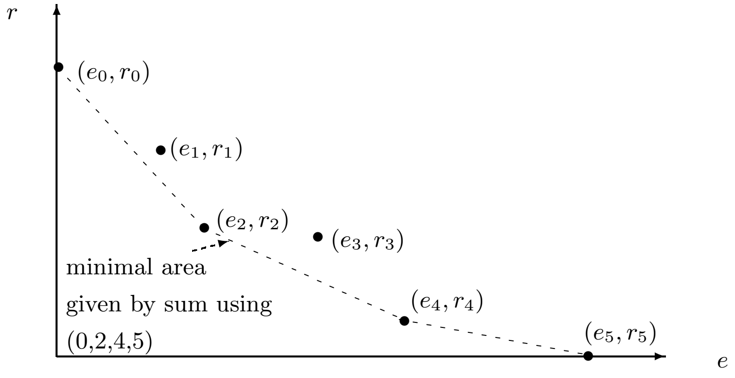
Theorem 2.5. [11] *Let $X \subset \mathbb{P}^n$ be a subvariety of dimension 1. If X is linearly semistable (resp. linearly stable), then X is Chow semistable (resp. Chow stable).*

Let $L_i \subset \mathbb{P}^n$ be the linear subspace defined by the sections in V_i and $P_{L_i} : \mathbb{P}^n - L_i \to \mathbb{P}(V_i)$ be the natural projection. Let $e_i := d - \deg P_{L_i}(X)$. Then we have the following theorem.

Theorem 2.6. [11] *Let X be a subvariety of $\mathbb{P}^n$ of dimension 1. Then*

$$e_F(X) \leq \min_{0=s_0<\cdots<s_l=n} \sum_{i=0}^{l-1} (r_{s_i} - r_{s_{i+1}})(e_{s_i} + e_{s_{i+1}}).$$

Remark 2.7. Plot the points (e_i, r_i) as shown in the below figure. The key observation is that the sum $\sum_{i=0}^{l-1}(r_{s_i} - r_{s_{i+1}})(e_{s_i} + e_{s_{i+1}})$ associated to a subsequence $0 = s_0 < \cdots < s_l = n$ represents twice the area in the first quadrant bounded by the axes and the curve obtained by joining the pairs of points (e_{s_i}, r_{s_i}) and $(e_{s_{i+1}}, r_{s_{i+1}})$. Taking the minimum of these sums over all such subsequences amounts to computing twice the area under the lower envelope of these points[11].



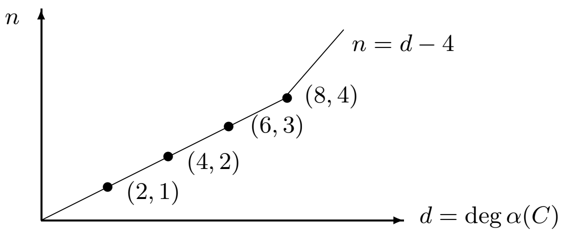
3. Chow stability of curves of genus 4 in $\mathbb{P}^3$

Now we want to understand the GIT quotient space

$$\mathrm{Chow}_{4,1}//\mathrm{SL}_4.$$

To do this, we need to have a criterion for the Chow stability.

3.1. **Chow stability of smooth curves.** Let C be a smooth curve of genus 4. Let $\alpha : C \to \mathbb{P}^3$ be a morphism defined by $|\omega_C|$. Then $\alpha(C) \subset \mathbb{P}^3$ corresponds to the point $(6, 3)$ in the following diagram.



By Riemann-Roch Theorem and Clifford Theorem on C, any projection of $\alpha(C) \subset \mathbb{P}^3$ corresponds to a point (d,n) below broken line with $d \leq 6$, $n < 3$ [11]. From the diagram and the above argument, it is clear that the slope does not increase. Therefore we conclude that $\alpha(C) \subset \mathbb{P}^3$ is linearly semistable and hence it is Chow semistable.

If C is nonhyperellitic, then α is an embedding. Since C is smooth and there is no degree 2 morphism form C to $\mathbb{P}^1$, we can see that $C \subset \mathbb{P}^3$ is linearly stable and hence it is Chow stable.

If C is a hyperelliptic curve of genus 4, $\alpha(C)$ is a double curve supported on a twisted cubic curve in $\mathbb{P}^3$. Hence we have the following proposition.

Proposition 3.1. *Let C be a hyperelliptic curve of genus 4. Let $\alpha : C \to \mathbb{P}^3$ be a morphism defined by $|\omega_C|$. Then $\alpha(C) \subset \mathbb{P}^3$ is strictly Chow semistable.*

Proof. From the above argument, we only need to show that it is not Chow stable. We know that $\alpha(C) = 2C_1$ where C_1 is a twisted cubic curve in $\mathbb{P}^3$. Let p be a point of C_1. Choose X_0,...,X_3 in $H^0(\mathbb{P}^3, \mathcal{O}_{\mathbb{P}^n}(1))$ such that $X_1,\ X_2,\ X_3$ vanish at p, $X_2,\ X_3$ vanish to order ≥ 2 at p, and X_3 vanishes to order ≥ 3 at p(i.e., $(X_3 = 0)$ is the osculating hyperplane at p). Let $r_0 = 3,\ r_1 = 2,\ r_2 = 1,\ r_3 = 0$. For the corresponding weighted flag F, $e_F(C) = 2e_F(C_1) \geq 2e_F(C_1)_p \geq 2 \cdot 9 = 3\sum r_i$ by Lemma 2.4. □

By the above results, we know that there is a birational map $\overline{M}_4 \dashrightarrow \mathrm{Chow}_{4,1}//\mathrm{SL}_4$ and all stable curves in the closure of hyperelliptic locus are identified in the quotient space.

3.2. **Some technical lemmas.**

In this section, we give some technical lemmas which will be used in calculating the bounds of the invariant $e_F(C)$ in the remaining sections.

Lemma 3.2. *Let C be a curve which is smooth at a point p. Let s generate the maximal ideal of $\mathcal{O}_{C,p}$. Let $R = \mathcal{O}_{C\times\mathbb{A}^1, p\times\{0\}} = \mathcal{O}_{C,p}[t]_{(s,t)}$, I an ideal of R, and $e(I) = \text{n.l.c.dim}_k(R/I^m)$. Then we have the following:*

1. *If $I = (t^a, s^b)$, then $e(I) = ab$.*
2. *If $I = (t^a, t^p s^q, s^b)$, then $e(I) \leq aq + bp$. Moreover if $\frac{p}{a} + \frac{q}{b} \leq 1$, then $e(I) = aq + bp$.*

Proof. (1) Since $I^m = (\{t^{an_1+r_1}s^{bn_2+r_2} | n_1 + n_2 \geq m, r_1 < a, r_2 < b\})$, the set of bases of R/I^m is

$$\{s^{bi+k}t^j | 0 \leq i \leq m-1, 0 \leq j \leq a(m-i)-1, 0 \leq k \leq b-1\}.$$

Therefore

$$\dim_k(R/I^m) = \sum_{i=0}^{m-1} a(m-i)b = ab(m^2+m)/2.$$

Hence $e(I) = \text{n.l.c.}\dim_k(R/I^m) = ab$.

(2) Since $I^m = (\{t^{an_1+r_1}(t^ps^q)^{n_2}s^{bn_3+r_2} | n_1+n_2+n_3 \geq m, r_1 < a, r_2 < b\})$, the following spans the vector space R/I^m. In particular, if $\frac{p}{a}+\frac{q}{b} \leq 1$, those form a basis of the vector space.

$$\begin{array}{cccc}
1 & s & \cdots & s^{bm-1} \\
t & ts & \cdots & ts^{bm-1} \\
 & \vdots & & \\
t^{p-1} & t^{p-1}s & \cdots & t^{p-1}s^{bm-1} \\
t^p & t^ps & \cdots & t^ps^{q-1} \\
t^{p+1} & t^{p+1}s & \cdots & t^{p+1}s^{q-1} \\
 & \vdots & & \\
t^{am-1} & t^{am-1}s & \cdots & t^{am-1}s^{q-1} \\
 & & & \\
(t^ps^q) & (t^ps^q)s & \cdots & (t^ps^q)s^{b(m-1)-1} \\
t(t^ps^q) & t(t^ps^q)s & \cdots & t(t^ps^q)s^{b(m-1)-1} \\
 & \vdots & & \\
t^{p-1}(t^ps^q) & t^{p-1}(t^ps^q)s & \cdots & t^{p-1}(t^ps^q)s^{b(m-1)-1} \\
t^p(t^ps^q) & t^p(t^ps^q)s & \cdots & t^p(t^ps^q)s^{q-1} \\
t^{p+1}(t^ps^q) & t^{p+1}(t^ps^q)s & \cdots & t^{p+1}(t^ps^q)s^{q-1} \\
 & \vdots & & \\
t^{a(m-1)-1}(t^ps^q) & t^{a(m-1)-1}(t^ps^q)s & \cdots & t^{a(m-1)-1}(t^ps^q)s^{q-1} \\
 & \vdots & & \\
 & \vdots & & \\
(t^ps^q)^{m-1} & (t^ps^q)^{m-1}s & \cdots & (t^ps^q)^{m-1}s^{b-1} \\
t(t^ps^q)^{m-1} & t(t^ps^q)^{m-1}s & \cdots & t(t^ps^q)^{m-1}s^{b-1} \\
 & \vdots & & \\
t^{p-1}(t^ps^q)^{m-1} & t^{p-1}(t^ps^q)^{m-1}s & \cdots & t^{p-1}(t^ps^q)^{m-1}s^{b-1} \\
t^p(t^ps^q)^{m-1} & t^p(t^ps^q)^{m-1}s & \cdots & t^p(t^ps^q)^{m-1}s^{q-1} \\
t^{p+1}(t^ps^q)^{m-1} & t^{p+1}(t^ps^q)^{m-1}s & \cdots & t^{p+1}(t^ps^q)^{m-1}s^{q-1} \\
 & \vdots & & \\
t^{a-1}(t^ps^q)^{m-1} & t^{a-1}(t^ps^q)^{m-1}s & \cdots & t^{a-1}(t^ps^q)^{m-1}s^{q-1}
\end{array}$$

Therefore

$$\dim_k(R/I^m) \leq \sum_{i=1}^{m} bpi + (ai-p)q = (aq+bp)(m^2+m)/2 - pqm.$$

Hence $e(I) = \text{n.l.c.}\dim_k(R/I^m) \leq aq+bp$ and the equality holds if $\frac{p}{a}+\frac{q}{b} \leq 1$. $\square$

Lemma 3.3. *Let F be the weighted flag of $H^0(\mathbb{P}^3, \mathcal{O}_{\mathbb{P}^3}(1))$ determined by coordinates X_0,...,X_3 and $r_0 \geq ... \geq r_3 = 0$. Let C be a curve which is not contained in the hyperplane $(X_3 = 0)$. Let $p \in C \cap (X_3 = 0)$. Suppose that C is smooth at p*

and $v_i = v(X_i)$ *where* v *is the of the natural valuation on* $\mathcal{O}_{C,p}$*. Then we have the following:*

1. *If* $p \notin (X_2 = X_3 = 0)$*, then* $e_F(C)_p = r_2 v_3$*.*
2. *If* $p \in (X_2 = X_3 = 0)$ *and* $p \neq (1,0,0,0)$*, then* $e_F(C)_p \leq r_1 v_3$*.*
3. *If* $p = (1,0,0,0)$*, then* $e_F(C)_p \leq r_0 v_3$ *and* $e_F(C)_p \leq r_0 + r_1 v_3$*.*

Proof. We will find the bounds by using Lemma 3.2. Note that $\mathcal{I}(C)_{p\times\{0\}} = (t^{r_0}s^{v_0}, t^{r_1}s^{v_1}, t^{r_2}s^{v_2}, s^{v_3})$ and $e_F(C)_p = \text{n.l.c.dim}\,(\mathcal{O}_{C\times\mathbb{A}^1, p\times\{0\}}/\mathcal{I}(C)^m_{p\times\{0\}})$.

Suppose $p \notin (X_2 = X_3 = 0)$. Then $v_2 = 0$. Thus $\mathcal{I}(C)_{p\times\{0\}} = (t^{r_2}, s^{v_3})$ and hence $e_F(C)_p = r_2 v_3$.

Assume $p \in (X_2 = X_3 = 0)$ and $p \neq (1,0,0,0)$. Then $v_1 = 0$. Therefore $\mathcal{I}(C)_{p\times\{0\}} > (t^{r_1}, s^{v_3})$ and hence $e_F(C)_p \leq r_1 v_3$.

Let $p = (1,0,0,0)$. Then $v_0 = 0$. Since $v_1 = 1$, $v_2 = 1$ or $v_3 = 1$, we have $\mathcal{I}(C)_{p\times\{0\}} > (t^{r_0}, s^{v_3})$ and $\mathcal{I}(C)_{p\times\{0\}} > (t^{r_0}, t^{r_1}s, s^{v_3})$. Therefore $e_F(C)_p \leq r_0 v_3$ and $e_F(C)_p \leq r_0 + r_1 v_3$. ☐

Remark 3.4. Let C be a smooth curve in $\mathbb{P}^3$ and $C \cap (X_3 = 0) = \sum a_i p_i + \sum b_j q_j + cp$ where $p = (1,0,0,0)$, $p_i (\neq p) \in (X_2 = X_3 = 0)$, and $q_j \notin (X_2 = X_3 = 0)$. Let $\sum a_i = a$ and $\sum b_j = b$. By the previous Lemma 3.3, we have

$$e_F(C) = \sum e_F(C)_{p_i} + \sum e_F(C)_{q_j} + e_F(C)_p \leq ar_1 + br_2 + cr_0$$

and

$$e_F(C) = \sum e_F(C)_{p_i} + \sum e_F(C)_{q_j} + e_F(C)_p \leq ar_1 + br_2 + (r_0 + cr_1).$$

Let $d := \deg C$. Then $e_F(C) \leq r_0 + dr_1$. If there exists a point in $C_1 \cap (X_3 = 0)$ which does not lie on $(X_2 = X_3 = 0)$, then $e_F(C) \leq r_0 + (d-1)r_1 + r_2$. If C meets $(X_3 = 0)$ at $p = (1,0,0,0)$ with multiplicity 1, then $e_F(C) \leq r_0 + (d-1)r_1$.

Lemma 3.5. *Let* F *be the weighted flag of* $H^0(\mathbb{P}^2, \mathcal{O}_{\mathbb{P}^2}(1))$ *determined by coordinates* X_0*,* X_1*,* X_2 *and* $r_0 \geq r_1 \geq r_2 = 0$*. Let* C *be a curve which is not contained in the hyperplane* $(X_2 = 0)$*. Let* $p \in C \cap (X_2 = 0)$*. Suppose that* C *is smooth at* p*. Let* $v_i = v(X_i)$ *where* v *is the natural valuation on* $\mathcal{O}_{C,p}$*. Then we have the following:*

1. *If* $p \neq (1,0,0)$ *then* $e_F(C)_p = r_1 v_2$*.*
2. *If* $p = (1,0,0)$ *then* $e_F(C)_p \leq r_0 v_2$ *and* $e_F(C)_p \leq r_0 + r_1 v_2$*.*

Proof. For the proof, we use Lemma 3.2.

Note that $\mathcal{I}(C)_{p\times\{0\}} = (t^{r_0}s^{v_0}, t^{r_1}s^{v_1}, s^{v_2})$ and $e_F(C)_p = \text{n.l.c.dim}\,(\mathcal{O}_{C\times\mathbb{A}^1, p\times\{0\}}/\mathcal{I}(C)^k_{p\times\{0\}})$.

Suppose $p \neq (1,0,0)$. Then $v_1 = 0$. Therefore $\mathcal{I}(C)_{p\times\{0\}} = (t^{r_1}, s^{v_2})$ and hence $e_F(C)_p = r_1 v_2$.

Assume $p = (1,0,0)$. Then $v_0 = 0$. Thus $\mathcal{I}(C)_{p\times\{0\}} > (t^{r_0}, s^{v_2})$, and hence $e_F(C)_p \leq r_0 v_2$. Since $v_1 = 1$ or $v_2 = 1$, we have $\mathcal{I}(C)_{p\times\{0\}} > (t^{r_0}, t^{r_1}s, s^{v_2})$. Therefore $e_F(C)_p \leq r_0 + r_1 v_2$. ☐

Remark 3.6. Let C be a smooth curve of degree d in $\mathbb{P}^2$ and $C \cap (X_2 = 0) = \sum a_i p_i + bp$ where $p = (1,0,0)$, $p_i \neq (1,0,0)$. Let $\sum a_i = a$. By the above Lemma 3.5, we have $e_F(C) \leq br_0 + ar_1$ and $e_F(C) \leq r_0 + dr_1$. If C meets $(X_2 = 0)$ at p with multiplicity 1, then $e_F(C) \leq r_0 + (d-1)r_1$.

Lemma 3.7. *Let* $R = k[X, Y]$*. For the ideal* $I = (t^a X, t^b Y)$ *of* $R[t]$*,*

$$\text{n.l.c. }\dim_k (R[t]/I^m)_m = a + b.$$

Proof. Since $I^m = (\{t^{ai+bj}X^iY^j | i+j=m\})$,

$$\begin{aligned}\dim_k(R[t]/I^m)_m &= \sum_{i+j=m} ai+bj = \sum_{i=0}^{m} ai+b(m-i) = \sum_{i=0}^{m} i(a-b)+mb \\ &= \frac{m(m+1)}{2}(a-b)+m(m+1)b = \frac{a+b}{2}(m^2+m).\end{aligned}$$

□

Lemma 3.8. *Let F be the weighted flag of $H^0(\mathbb{P}^3, \mathcal{O}_{\mathbb{P}^3}(1))$ determined by coordinates X_0,...,X_3 and $r_0 \geq ... \geq r_3 = 0$. Let L be a line which is contained in the hyperplane $(X_3 = 0)$. Then $e_F(L)$ is as follows:*

1. *If $L = (X_2 = X_3 = 0)$, then $e_F(L) = r_0 + r_1$.*
2. *If $L = (X_0 = aX_1 + bX_2, X_3 = 0)$ for some a and b, then $e_F(L) = r_1 + r_2$.*
3. *If $L = (X_1 = aX_2, X_3 = 0)$, then $e_F(L) = r_0 + r_2$.*

Proof. Let R be the homogeneous coordinate ring of L. Let I be the ideal in $R[t]$ which is generated by $\{X_i t_i^r | i = 0, ..., 3\}$. Then $e_F(L) = \text{n.l.c.}\dim_k(R[t]/I^m)_m$.

In case (1), $R = k[X_0, X_1]$ and $I = (X_0t^{r_0}, X_1t^{r_1})$. In case (2), $R = k[X_1, X_2]$ and $I = (X_1t^{r_1}, X_2t^{r_2})$. In case (3), $R = k[X_0, X_2]$ and $I = (X_0t^{r_0}, X_2t^{r_2})$. Thus, from Lemma 2.3 and Lemma 3.7, the results follow. □

Lemma 3.9. *Let F be the weighted flag of $H^0(\mathbb{P}^3, \mathcal{O}_{\mathbb{P}^3}(1))$ determined by coordinates X_0,...,X_3 and $r_0 \geq \cdots \geq r_3 = 0$. Let L be a line which is not contained in the hyperplane $(X_3 = 0)$. Let $L \cap (X_3 = 0) = p$. Then we have the following :*

1. *If $p = (1, 0, 0, 0)$, then $e_F(L) = r_0$.*
2. *If $p \neq (1, 0, 0, 0)$ and $p \in (X_2 = X_3 = 0)$, then $e_F(L) = r_1$.*
3. *If $p \notin (X_2 = X_3 = 0)$, then $e_F(L) = r_2$.*

Proof. We have $\mathcal{I}(L)_{p\times\{0\}} = (t^{r_0}s^{v_0}, t^{r_1}s^{v_1}, t^{r_2}s^{v_2}, s)$ and $e_F(L) = e_F(L)_p$ since L is not contained in $(X_3 = 0)$.

Suppose $p = (1, 0, 0, 0)$. Then $v_0 = 0$ and hence $\mathcal{I}(L)_{p\times\{0\}} = (t^{r_0}, s)$. Therefore $e_F(L)_p = r_0$.

Suppose $p \neq (1, 0, 0, 0)$ and $p \in (X_2 = X_3 = 0)$. Then $v_1 = 0$ and $v_2 \neq 0$. Thus $\mathcal{I}(L)_{p\times\{0\}} = (t^{r_1}, s)$ and hence $e_F(L)_p = r_1$.

Suppose $p \notin (X_2 = X_3 = 0)$. Then $v_2 = 0$ and hence $\mathcal{I}_{p\times\{0\}}(L) = (t^{r_2}, s)$. Thus $e_F(L)_p = r_2$. □

Lemma 3.10. *Let C be a curve in $\mathbb{P}^n$ which is contained in a hyperplane $H = (X_n = 0) = \mathbb{P}^{n-1} \subset \mathbb{P}^n$. Let F be the weighted flag $H^0(\mathbb{P}^n, \mathcal{O}_{\mathbb{P}^n}(1))$ determined by coordinates X_0,...,X_n and $r_0 \geq ... \geq r_n = 0$. Let $F|_H$ be the weighted flag of $H^0(\mathbb{P}^{n-1}, \mathcal{O}_{\mathbb{P}^{n-1}}(1))$ determined by $r_0 \geq ... \geq r_{n-1}$ and coordinates X_0,...,X_{n-1} which is induced from that of F by restriction. Then $e_F(C) = e_{F|_H}(C)$.*

Let F' be the weighted flag of $H^0(\mathbb{P}^{n-1}, \mathcal{O}_{\mathbb{P}^{n-1}}(1))$ determined by coordinates X_0,...,X_{n-1} and $r'_0 = r_0 - r_{n-1} \geq r'_1 = r_1 - r_{n-1} ... \geq r'_{n-1} = r_{n-1} - r_{n-1} = 0$. Then

$$e_F(C) - \frac{2}{n}\deg C \sum_{i=0}^{n-1} r_i = e_{F'}(C) - \frac{2}{n}\deg C \sum_{i=0}^{n-1} r'_i.$$

Proof. This is clear from the proof of Theorem 2.9 in [11]. □

3.3. **Chow stability of irreducible curves.** In this section, we discuss the Chow stability of irreducible curves of genus 4 and degree 6 in $\mathbb{P}^3$.

In the following, a cusp means a double point of a curve with one inverse point under the normalization map and an ordinary cusp means a cusp which is locally written by $(y^2 = x^3)$.

Lemma 3.11. *Let C be a reduced, irreducible and nondegenerate curve of genus 4 and degree 6 in $\mathbb{P}^3$. Assume that C has at most nodes, ordinary cusps, and tacnodes as its singularities. Then there is no line $L \subset \mathbb{P}^3$ such that* $\deg P_L(C) = 1$ *where P_L is the projection with center L.*

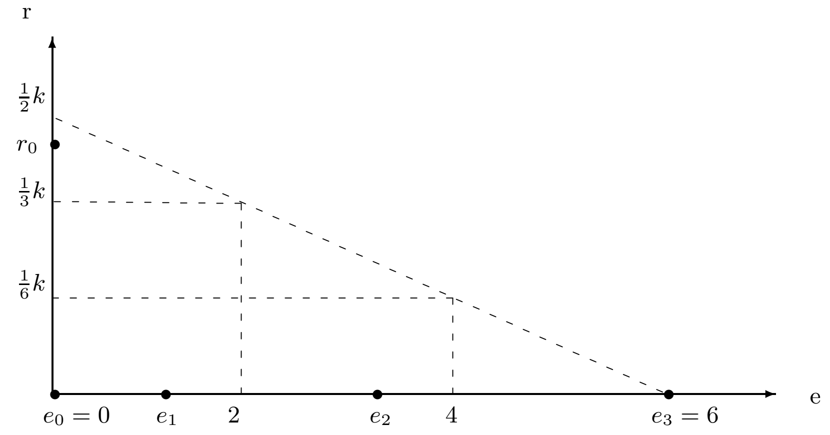
Proof. Suppose that there is a line $L \subset \mathbb{P}^3$ such that $\deg P_L(C) = 1$. Then, by composition of P_L and the normalization $\tilde{C} \to C$, we have a regular morphism $\alpha_L : \tilde{C} \to \mathbb{P}^1$ of degree 1. Then, by Hurwitz's theorem, $g(\tilde{C}) = 0$. Since $\deg \alpha_L = 1$, every singular point of C lies on L. Because $\deg C = 6$ and C is nondegenerate, C has at most two double points. So the only possible case is that C has two tacnodes and L passes through the tacnodes p, q and another point $r \in C$. Let p_1, $p_2 \in \tilde{C}$ be the inverse image of p. Choose coordinates X_0,..., X_3 so that X_2, X_3 vanish to order ≥ 2 at p_1 and p_2. Let $L^{'}$ is the line defined by $X_2 = X_3 = 0$. By the degree consideration, we can see that $L^{'}$ does not coincide with L. Let H be the plane determined by L and $L^{'}$. Then the number of points in $H \cap C$ is greater than or equal to 7 with multiplicity. This contradicts the degree assumption. □

Theorem 3.12. *Let C be a reduced, irreducible, and nondegenerate curve of genus 4 and degree 6 in $\mathbb{P}^3$. Assume that C has at most nodes, ordinary cusps, and tacnodes as its only singularities. Then C is Chow semistable. Moreover C is strictly Chow semistable if and only if C has a tacnode and there is a hyperplane H meeting with multiplicity 3 at each inverse point of the tacnode in $\tilde{C}$ where $\tilde{C}$ is the normalizaion of C.*

Proof. Consider a weighted flag F of $H^0(\mathbb{P}^3, \mathcal{O}_{\mathbb{P}^3}(1))$ determined by a filtration $H^0(\mathbb{P}^3, \mathcal{O}_{\mathbb{P}^3}(1)) = V_0 \supset \cdots \supset V_3$ where each V_i is a vector space of dimension $4 - i$ and a set of integers $r_0 \geq \cdots \geq r_3 = 0$ such that $\sum r_i = k$. Since C has at most double points, $e_1 \leq 2$. From the previous Lemma 3.11, $e_2 \leq 4$. Clearly, $e_0 = 0$ and $e_3 = 6$. Thus, by Theorem 2.6, we have the following inequality:

$$\begin{aligned} e_F(C) &\leq (r_0 - r_1)(e_0 + e_1) + (r_1 - r_2)(e_1 + e_2) + (r_2 - r_3)(e_2 + e_3) \\ &= e_1(r_0 - r_2) + e_2 r_1 + e_3 r_2 \leq 2(r_0 - r_2) + 4r_1 + 6r_2 = 4k - 2r_0. \end{aligned}$$

Note that $4k - 2r_0 \geq 3\sum r_i = 3k$ if and only if $r_0 \leq k/2$. Hence if $r_0 > k/2$, then $e_F(C) < 3k$. Therefore, we may assume $r_0 \leq k/2$. Consider the following diagram.



Since the twice of the area in the first quadrant bounded by joining the pairs of points (e_{s_i}, r_{s_i}) and $(e_{s_{i+1}}, r_{s_{i+1}})$ is $\leq 3k$, we have $e_F(C) \leq 3k$. Therefore, C is Chow semistable. Note that the equality holds if and only if $e_1 = 2$, $e_2 = 4$, $r_0 = k/2$, $r_1 = k/3$ and $r_2 = k/6$.

If $e_2 = 4$, the map $C \dashrightarrow \mathbb{P}^1$ induced from the projection defined by V_2 gives a morphism $\tilde{C} \to \mathbb{P}^1$ of degree 2. Thus we can conclude that if the normalization $\tilde{C}$ of C is nonhyperelliptic, C is Chow stable.

Now we only need to consider the case $e_1 = 2$, $e_2 = 4$, $r_0 = 3$, $r_1 = 2$, $r_2 = 1$, $r_3 = 0$. Let $p = (1, 0, 0, 0)$.

CASE 1. $C \cap (X_3 = 0) \neq 6p$:

Let $C \cap (X_3 = 0) = ap + \sum a_i p_i$ where $a \neq 6$. Then $e_F(C) \leq r_0 a + r_1 \sum a_i = 3a + 2\sum a_i = 12 + a \leq 17 < 18 = 3\sum r_i$.

CASE 2. $C \cap (X_3 = 0) = 6p$:

Since $e_1 = 2$ and $e_2 = 4$, p is a node or tacnode. Let $\tilde{C}$ be the normalization C. Let p_1, p_2 be the inverse points of p in $\tilde{C}$. Let $\mathcal{I}(C)_{p_1 \times \{0\}} = (t^3, t^2 s^{a_1}, ts^{b_1}, s^{c_1})$ and $\mathcal{I}(C)_{p_2 \times \{0\}} = (t^3, t^2 s^{a_2}, tb^{b_2}, s^{c_2})$. Then $c_1 + c_2 = 6$. Since $e_2 = 4$, $\min(b_1, c_1) + \min(b_2, c_2) = 4$.

CASE 2.1 p is a nodal point of C:

Since p is a nodal point, we may assume that $\min(b_1, c_1) = 1$ and $\min(b_2, c_2) = 3$. Thus $\mathcal{I}(C)_{p_1 \times \{0\}} > (t^3, ts, s^{c_1})$ and $\mathcal{I}(C)_{p_2 \times \{0\}} > (t^3, t^2 s, s^{c_2})$. Hence we get $e_F(\tilde{C})_{p_1} \leq 3 + c_1$ and $e_F(\tilde{C})_{p_2} \leq 3 + 2c_2$. Therefore $e_F(C) = e_F(\tilde{C})_{p_1} + e_F(\tilde{C})_{p_2} \leq (3 + c_1) + (3 + 2c_2) = 12 + c_2 \leq 17 < 18 = 3\sum r_i$.

CASE 2.2 p is a tacnode:

In this case $\min(b_1, c_1) = \min(b_2, c_2) = 2$.

If c_1=2 and $c_2 = 4$, $\mathcal{I}(C)_{p_1 \times \{0\}} > (t^3, s^2)$ and $\mathcal{I}(C)_{p_2 \times \{0\}} > (t^3, ts^2, s^4)$ and hence $e_F(C) = e_F(\tilde{C})_{p_1} + e_F(\tilde{C})_{p_2} \leq 6 + 10 = 16 < 18 = 3\sum r_i$.

Suppose $c_1 = c_2 = 3$ i.e X_3 vanish to order 3 at p_1, p_2. Since $\min(b_1, c_1) = \min(b_2, c_2) = 2$, X_2 vanish to order 2 at p_1, p_2. Hece, by Lemma 2.4, $e_F(C) = e_F(\tilde{C})_{p_1} + e_F(\tilde{C})_{p_2} \geq 9 + 9 = 3\sum r_i$. Thus, this is the only case such that C is strictly Chow semistable. □

Proposition 3.13. *Let $C \subset \mathbb{P}^3$ be a curve of degree 6. If C has a cusp which is not ordinary, then C is Chow unstable.*

Proof. Let $\tilde{C}$ be a normalization of C and $p \in \tilde{C}$ be the inverse image of the cusp. We can choose $X_0, ..., X_3$ in $H^0(\mathbb{P}^3, \mathcal{O}_{\mathbb{P}^3}(1))$ so that X_1, X_2, X_3 vanish at p and X_2, X_3 vanish at p to order ≥ 5. Let $r_0 = 5$, $r_1 = 3$, $r_2 = r_3 = 0$. Then $e_F(C) = e_F(\tilde{C})_p \geq 25 > 3\sum r_i = 24$ by Lemma 2.4. □

3.4. **Chow stability of nonreduced curves.** In this section, we study the Chow stability of noreduced curves in $\mathbb{P}^3$ of degree 6. We show that the only nonreduced Chow semistable curve whose Chow form lies on $\mathrm{Chow}_{4,1}$ is of the form $2C_1$ where C_1 is a twisted cubic curve in $\mathbb{P}^3$. Since every twisted cubic curve in $\mathbb{P}^3$ is projectively equivalent, this shows that there is only one point in $\mathrm{Chow}_{4,1}//\mathrm{SL}_4$ which is represented by a nonreduced curve.

Lemma 3.14. *Let $C \subset \mathbb{P}^3$ be a curve of degree 6 with a singular point of multiplicity at least 3. Then X is not Chow stable. Furthermore, if C has a point of multiplicity at least 4, then it is Chow unstable.*

Proof. Let $p \in C$ be a point of multiplicity at least 3. Take coordinates X_0,...,X_3 so that $p = (1, 0, 0, 0)$ and let $r_0 = 1$, $r_1 = r_2 = r_3 = 0$. Let F be the associated weighted flag. Let $\mathcal{I}$ be the ideal sheaf of $\mathcal{O}_{X \times \mathbb{A}^1}$ defined by

$$\mathcal{I} \cdot [\mathcal{O}_C(1) \otimes \mathcal{O}_{\mathbb{A}^1}] = \text{the subsheaf generated by } t^{r_i} X_i \ (i = 0, ..., 3).$$

Then $\mathcal{I}_{p \times \{0\}} = (t, M_p)\mathcal{O}_{C \times \mathbb{A}^1, p \times \{0\}}$ is the maximal ideal of $\mathcal{O}_{C \times \mathbb{A}^1, p \times \{0\}}$. Hence

$$e_F(C) = e_F(C)_p = \mathrm{mult}_{(p,0)}(C \times \mathbb{A}^1) = \mathrm{mult}_p C \geq 3 = 3\sum r_i.$$

□

Lemma 3.15. *Let $C \subset \mathbb{P}^3$ be a curve of degree 6. Suppose $C = C_1 + nC_2$ where C_2 is an irreducible curve and $n \geq 2$, and C_1 and C_2 have no common components. Then C is not Chow stable.*

Proof. Choose $p \in C_1 \cap C_2$. By Lemma 3.14, we may assume that C_1 and C_2 are smooth at p. Take coordinates X_0,...,X_3 so that $p = (1, 0, 0, 0)$ and let $r_0 = 1$, $r_1 = r_2 = r_3 = 0$. Let F be the associated weighted flag. Then

$$e_F(C) \geq e_F(C_1)_p + n e_F(C_2)_p \geq 1 + 2 = 3 = 3\sum r_i.$$

□

Theorem 3.16. *Every Chow semistable curve whose Chow form lies on* $\mathrm{Chow}_{4,1}$ *is reduced except double curves supported on a twisted cubic curve.*

Proof. Let C be a nonreduced Chow semistable curve of degree 6 whose Chow form lies on $\mathrm{Chow}_{4,1}$.

Suppose that $C = nC_1$ for a reduced curve C_1 in $\mathbb{P}^3$ and $n \geq 2$. From Lemma 3.14, we can see that C_1 is a smooth curve. If $n > 2$, then $\deg C_1 = 2$ or 1 and hence C is degenerate. Since every degenerated curve is unstable, we can conclude that $n = 2$. If C_1 is a smooth cubic curve which is not a twisted cubic curve, then it is degenerate. Hence C_1 is a twisted cubic curve.

Assume that $C = nC_1+C_2$ for some reduced curve C_1 and $n \geq 2$. Let $p \in C_1 \cap C_2$. By Lemma 3.14, we can see that $n = 2$ and C_1, C_2 are smooth at p. Thus $\deg C_1 = 1$ and $\deg C_2 = 4$, or $\deg C_1 = \deg C_2 = 2$. We will consider these two cases.

Case 1. $\deg C_1 = \deg C_2 = 2$:

Suppose that C_1 meets C_2 transversely at p. Take coordinates X_0,...,X_3 so that $p = (1, 0, 0, 0)$, $(X_3 = X_2 = 0)$ is the tangent line of C_1 at p, and $(X_3 = X_1 = 0)$ is the tangent line of C_2 at p. Let $r_0 = 2$, $r_1 = 1$, $r_2 = r_3 = 0$. Let F be the associated weighted flag. Then $\mathcal{I}(C_1)_{p\times\{0\}} = (t^2, ts, s^2)$ and $\mathcal{I}(C_2)_{p\times\{0\}} = (t^2, s)$. Hence $e_F(C_1) \geq e_F(C_1)_p = 4$ and $e_F(C_2) \geq e_F(C_2)_p = 2$. Therefore

$$e_F(C) = 2e_F(C_1) + e_F(C_2) \geq 2 \cdot 4 + 2 = 10 > 9 = 3\sum r_i.$$

This contradicts the assumption.

Assume that C_1 and C_2 have a common tangent line at p. Take coordinates X_0,...,X_3 so that $p = (1, 0, 0, 0)$ and $(X_2 = X_3 = 0)$ is the common tangent line at p. Let $r_0 = 2$, $r_1 = 1$, $r_2 = r_3 = 0$. Then $\mathcal{I}(C_1)_{p\times\{0\}} = (t^2, ts, s^2)$ and $\mathcal{I}(C_2)_{p\times\{0\}} = (t^2, ts, s^2)$. Hence $e_F(C_1) \geq e_F(C_1)_p = 4$ and $e_F(C_2) \geq e_F(C_2)_p = 4$. Therefore

$$e_F(C) = 2e_F(C_1) + e_F(C_2) \geq 2 \cdot 4 + 4 = 12 > 9 = 3\sum r_i.$$

We have a contradiction.

Case 2. $\deg C_1 = 1$ and $\deg C_2 = 4$:

In this case, C_1 meets C_2 transversely. In fact, suppose C_1 is the tangent line of C_2 at $p \in C_1 \cap C_2$. Take coordinates X_0,...,X_3 so that $C_1 = (X_2 = X_3 = 0)$ and $p = (1, 0, 0, 0)$. Let $r_0 = 2$, $r_1 = 1$, $r_2 = r_3 = 0$. Let F be the associated weighed flag. Then $\mathcal{I}(C_2)_{p\times\{0\}} = (t^2, ts, s^v)$ where $v \geq 2$ and hence $e_F(C_2) \geq 4$. Moreover, $e_F(C_1) = r_0 + r_1 = 3$ by Lemma 3.8. Therefore we have

$$e_F(C) = 2e_F(C_1) + e_F(C_2) \geq 10 > 9 = 3\sum r_i.$$

This contradicts the assumption.

The number of points in $C_1 \cap C_2$ is less than or equal to 2. Indeed, suppose the number of points in $C_1 \cap C_2$ is greater than or equal to 3. Take coordinates X_0,...,X_3 so that $C_1 = (X_2 = X_3 = 0)$ and $p = (1, 0, 0, 0)$. Let $r_0 = 1$, $r_1 = 1$, $r_2 = r_3 = 0$. Let F be the associated weighted flag. Then $e_F(C_1) = 2$ and $e_F(C_2) \geq 3$. Hence

$$e_F(C) = 2e_F(C_1) + e_F(C_2) \geq 7 > 6 = 3\sum r_i.$$

We have a contradiction.

Since C lies in a quadric surface in $\mathbb{P}^3$, we have the following three subcases.

Case 2.1. C is contained in the union of two hyperplanes:

Let H be the hyperplane containing C_2. Since C is nondegenerate, C_1 is not contained in H and hence C_1 meets C_2 at exactly one point p. Take coordinates X_0,...,X_3 so that $H = (X_3 = 0)$, $C_1 = (X_1 = X_2 = 0)$ and $p = (1, 0, 0, 0)$. Let $r_0 = r_1 = r_2 = 1$ and $r_3 = 0$. Let F be the associated weighted flag. Then $e_F(C_1) = 1$ by Lemma 3.9 and $e_F(C_2) = 8$ by Lemma 2.2. Hence

$$e_F(C) = 2e_F(C_1) + e_F(C_2) = 10 > 9 = 3\sum r_i.$$

We have a contradiction.

Case 2.2. C lies in a smooth quadric surface Q:

Let $C_1 = (0,1)$ and $C_2 = (a,b)$ as divisors of Q. Since the degree of C_2 is 4, $a+b=4$.

Suppose C_1 meets C_2 at exactly one point. Then $a=1$ and $b=3$. Thus $C = 2C_1 + C_2 = (1,5)$ and hence $g(C)=0$. This contradicts the assumption.

Assume that C_1 meets C_2 at two distinct points. Then $a=b=2$. Thus $C = 2C_1 + C_2 = (2,4)$ and hence $g(C)=3$. This gives us a contradiction.

Case 2.3. C lies in a quadric cone Q:

Since C_2 is not plane curve with $\deg C_2 = 4$, we get $g(C_2)=1$. Let $\pi : \tilde{Q} \to Q$ be the blowing up of Q at the singular point q of Q. Then $\tilde{Q}$ is a smooth surface. Let $\bar{C} = \pi^*C$, $\bar{C}_1 = \pi^*C_1$ and $\bar{C}_2 = \pi^*C_2$. Since C_1 is a line, it passes through the singular point of Q. Hence $\bar{C}_1 = \tilde{C}_1 + E$ where $\tilde{C}_1$ is the proper transform of C_1 and E is the exceptional curve. Since $K_{\tilde{Q}} = \pi^*K_Q$ and $K_Q = \mathcal{O}_Q(-2)$, $K_{\tilde{Q}} \cdot (\tilde{C}_1 + E) = \pi^*K_Q \cdot \pi^*C_1 = -2$. Hence $K_{\tilde{Q}} \cdot \tilde{C}_1 = -2$. By the adjunction theorem, $\tilde{C}_1^2 = 0$. Thus

$$g(2\bar{C}_1) = 2g(\bar{C}_1) + \bar{C}_1^2 - 1 = (\tilde{C}_1 + E)^2 - 1 = \tilde{C}_1^2 + 2\tilde{C}_1 \cdot E + E^2 - 1 = -1$$

since $g(\bar{C}_1) = 0$, $E^2 = -2$, and $\tilde{C}_1 \cdot E = 1$. Therefore

$$g(\bar{C}) = g(2\bar{C}_1) + g(\bar{C}_2) + 2\bar{C}_1 \cdot \bar{C}_2 - 1 = -1 + 1 + 2\bar{C}_1 \cdot \bar{C}_2 - 1 = 2\bar{C}_1 \cdot \bar{C}_2 - 1 \leq 3$$

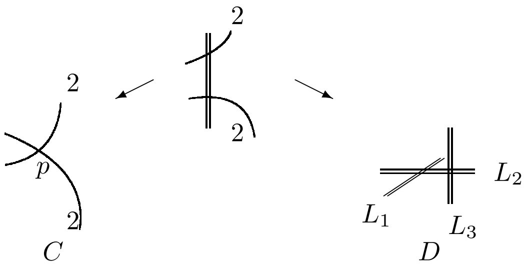
since the C_1 meets C_2 in at most 2 points. We have a contradiction.

In all, we proved the Theorem. □

3.5. **Chow stability of curves with two components.** Now we consider a genus 4 stable curve C consisting of two smooth components C_1 and C_2. Then $|\omega_C|$ is base point free (resp. very ample) if and only if C_1 meets C_2 in at least two points (resp. three points and C is not in the closure of the hyperelliptic locus) [3] [10].

Lemma 3.17. *All stable curves of genus 4 in the boundary divisor* δ_2 *are identified in* $\mathrm{Chow}_{4,1}//\mathrm{SL}_4$.

Proof. Let ${\delta_2}^0$ be the locus of curves C in the boundary divisor δ_2 such that $C = C_1 + C_2$ where C_1, C_2 are smooth curves of genus 2. Then the image of C under the linear system $|\omega_C|$ after blowing up at the base point $p = C_1 \cap C_2$ is a curve $D = 2(L_1 + L_2 + L_3)$ where L_i is a line for $i = 1,2,3$, L_1 and L_2 generate a plane, L_2 and L_3 generate another plane.



We note that, in $\mathrm{Chow}_{4,1}//\mathrm{SL}_4$, all hyperelliptic curves are identified to the point which is represented by double curves supported on a twisted cubic curve.

Let C be a curve in $\delta_2\cap$ (the closure of hyperelliptic locus). Then there is a flat family $\mathcal{C} \to B$ of curves parametrized by a smooth curve B such that the fiber C_0 over $0 \in B$ is equal to C and the generic fibers are hyperelliptic. Since the generic fibers are identified to a point in $\mathrm{Chow}_{4,1}//\mathrm{SL}_4$ and GIT quotient is projective, C is replaced by the same point.

Let C be a curve in ${\delta_2}^0$. Then there is a flat family $\mathcal{C} \to B$ of curves parametrized by a smooth curve B such that the fiber C_0 over $0 \in B$ is equal to C and the generic fibers are smooth. The canonical image of $\mathcal{C}$ forms a family $\mathcal{D} \to B$ of curves in $\mathbb{P}^3$ with fiber D_0 over 0 equal to a curve of type D and the generic fibers are nonhyperelliptic smooth curves in $\mathbb{P}^3$. Since all curves of type D is projectively equivalent, by an automorphism in $\mathbb{P}^3$, we get a new family $\mathcal{D}' \to B$ of curves in $\mathbb{P}^3$ such that the fiber D'_0 over 0 is the canonical image of a curve in $\delta_2\cap$ (the closure of hyperelliptic locus). We know that the semistable model of D'_0 is a double curve supported on a twisted cubic curve. Since the two families $\mathcal{D}$ and $\mathcal{D}'$ are projectively equivalent, we can see that the semistable model of D_0 is the same as that of D'_0.

Let C be a curve in δ_2. Then we have a flat family $\mathcal{C} \to B$ parametrized by a smooth curve B such that the fiber C_0 over $0 \in B$ is equal to C and the generic fibers are in δ_2^0. Since the generic fibers are identified to a point in $\mathrm{Chow}_{4,1}//\mathrm{SL}_4$ and GIT quotient is projective, C_0 is replaced by the same point. □

Suppose that C_1 meets C_2 in at most two points. We note that an elliptic tail in a stable curve of genus 4 is replaced by a curve with a cusp by Theorem 3.12, and that all stable curves of genus 4 in the boundary divisor δ_2 are identified in the moduli space of Chow semistable curves of genus 4 in $\mathbb{P}^3$ by Lemma 3.17. An elliptic bridge in a stable curve of genus 4 is replaced by a curve with a tacnode. The following figure shows these correspondences.

Therefore, it remains to consider the cases when C_1 meets C_2 in at least three points. In this case, C is one of the following types.

TYPE1 C_1 meets C_2 transversely at 3 points, $g(C_1) = 1$, and $g(C_2) = 1$.
We call this curve as a 3-pointed elliptic tail.
TYPE2 C_1 meets C_2 transversely at 3 points, $g(C_1) = 2$, and $g(C_2) = 0$.
TYPE3 C_1 meets C_2 transversely at 4 points.
In this case, $g(C_1) = 1$ and $g(C_2) = 0$.
TYPE4 C_1 meets C_2 transversely at 5 points.
In this case, $g(C_1) = g(C_2) = 0$.

Proposition 3.18. *Let C be a curve of* TYPE1. *Then C is Chow semistable.*

Proof. As a curve in $\mathbb{P}^3$ which is embedded by $|\omega_C|$, C_1, C_2 are curves of degree 3 which are contained in hyperplanes H_1, H_2 respectively. Moreover all intersection points are contained in the line $H_1 \cap H_2$.

Let F be the weighted flag determined by $r_0 \geq \cdots \geq r_3 = 0$ and X_0,...,$X_3 \in H^0(\mathbb{P}^3, \mathcal{O}_{\mathbb{P}^3}(1))$. Let $L := (X_2 = X_3 = 0)$.

CASE 1. $H_i \neq (X_3 = 0)$ for $i = 1, 2$:

Suppose $H_1 \cap H_2 = L$. Then $C_i \cap (X_3 = 0)$ consists of three distinct points for i=1,2. Hence $e_F(C_i) \leq r_0 + 2r_1$ for $i = 1, 2$ by Remark 3.4. Therefore

$$e_F(C) = e_F(C_1) + e_F(C_2) \leq (r_0 + 2r_1) + (r_0 + 2r_1) \leq 3\sum r_i.$$

Assume $H_1 \cap H_2 \neq L$. Then we may assume that L is not contained in H_1. Hence there is at most one point in $C_1 \cap (X_3 = 0)$ which is contained in L. In particular, L is not the tangent line at any point of C_1. If there exists a point p in $C_1 \cap (X_3 = 0)$ which lies on L, then

$$\mathcal{I}(C_1)_{p\times\{0\}} = (t^{r_0}s^{v_0}, t^{r_1}s^{v_1}, t^{r_2}s^{v_2}, s^{v_3}) > (t^{r_0}, t^{r_2}s, s^{v_3})$$

since L is not the tangent line of C_1 at p, and hence $e_F(C_1)_p \leq r_0 + v_3 r_2$. Therefore

$$e_F(C_1) = \sum_{p\in L} e_F(C_1)_p + \sum_{p\notin L} e_F(C_1)_p \leq r_0 + 3r_2.$$

Thus $e_F(C) = e_F(C_1) + e_F(C_2) \leq (r_0 + 3r_2) + (r_0 + 3r_1) < 3\sum r_i$.

CASE 2. $H_1 = (X_3 = 0)$:

Let F' be the filtration of $H_1 = \mathbb{P}^2$ associated with weights $r'_0 = r_0 - r_2, r'_1 = r_1 - r_2, r'_2 = r_2 - r_2 = 0$ and with coordinates X_0, X_1, X_2 which are induced from F. Then, by Lemma 3.10,

$$e_F(C_1) - 2(r_0 + r_1 + r_2) = e_{F'}(C_1) - 2(r'_0 + r'_1 + r'_2) = e_{F'}(C_1) - (2r_0 + 2r_1 - 4r_2).$$

Hence $e_F(C_1) = e_{F'}(C_1) + 6r_2$.

CASE 2.1. $H_1 \cap H_2 \neq L$:

Then $e_{F'}(C_1) \leq r'_0 + 3r'_1 = r_0 + 3r_1 - 4r_2$ by Remark 3.6. Since there exists at least one points in $C_2 \cap (X_3 = 0)$ which does not lie on L, we have $e_F(C_2) \leq r_0 + 2r_2$ by Remark 3.4. Thus

$$\begin{aligned} e_F(C) = e_F(C_1) + e_F(C_2) &\leq (r_0 + 3r_1 + 2r_2) + (r_0 + 2r_2) \\ &= 2r_0 + 3r_1 + 4r_2 \leq 3\sum r_i. \end{aligned}$$

CASE 2.2. $H_1 \cap H_2 = L$:

Since C_i meets L at three distinct points for i=1,2, we have $e_{F'}(C_1) \leq r'_0+2r'_1 = r_0 + 2r_1 - 3r_2$ by Remark 3.6 and $e_F(C_2) \leq r_0 + 2r_1$ by Remark 3.4. Hence

$$\begin{aligned} e_F(C) &= e_F(C_1) + e_F(C_2) \leq (r_0 + 2r_1 + 3r_2) + (r_0 + 2r_1) \\ &= 2r_0 + 4r_1 + 3r_2 \leq 3 \sum r_i. \end{aligned}$$

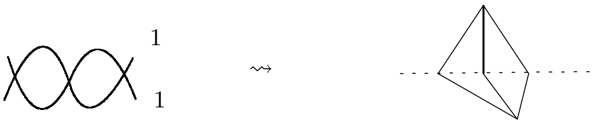
In all, we showed that C is Chow semistable. Moreover, in the proof of Theorem 3.20, we can conclude that C is strictly Chow semistable ☐

Let $\tilde{C_1} = L_{1,1} + L_{1,2} + L_{1,3}$ and $\tilde{C_2} = L_{2,1} + L_{2,2} + L_{2,3}$ where each $L_{i,j}$ is a line. Suppose that $\tilde{C_i}$ is contained in a plane H_i and the three lines $L_{i,1}$, $L_{i,2}$, $L_{i,3}$ intersect at a point q_i for each $i = 1, 2$. Suppose that $L_{1,j}$ and $L_{2,j}$ meet at p_j for $j = 1, 2, 3$. Let $\tilde{C} = \tilde{C_1} + \tilde{C_2}$. It is well known to experts that $\tilde{C}$ is Chow semistable(ref. section 11.3 in [1]). And, by Lemma 3.14, it is not Chow stable. Hence we have the following proposition.

Proposition 3.19. *Let $\tilde{C} \subset \mathbb{P}^3$ be a curve as above. Then $\tilde{C}$ is strictly Chow semistable.*

Theorem 3.20. *All curves of* Type1 *are identified in the moduli space of curves of genus 4 in $\mathbb{P}^3$.*

Proof. Let C be a curve of Type1. Choose coordinates X_0, X_1, X_2, X_3 so that $C_1 = (X_0X_2^2 = X_1(X_1 - a_1X_0)(X_1 - b_1X_0), X_3 = 0)$ and $C_2 = (X_0X_3^2 = X_1(X_1 - a_1X_0)(X_1 - b_1X_0), X_2 = 0)$. Consider one parameter subgroup $\lambda(t) = \text{diag}(t^{-1}, t^{-1}, t, t)$. Then the limit of C under the action λ is the curve in Proposition 3.19. Any two curves of the type in Proposition 3.19 are projectively equivalent to each other and hence we get the proof.



(general 3-pointed elliptic tail) ☐

The proof of the above Theorem shows that any curve C of Type1 has a strictly Chow semistable flat limit by a one parameter subgroup. Thus C is not Chow stable and hence C is strictly Chow semistable.

Now we consider a curve of Type2.

Proposition 3.21. *Let $C \subset \mathbb{P}^3$ be a curve of* Type2. *Then C is Chow stable.*

Proof. As a canonical curve in $\mathbb{P}^3$ embedded by $|\omega_C|$, we have $\deg C_1 = 5$ and $\deg C_2 = 1$.

Let F be the weighted flag determined by X_0,...,$X_3 \in H^0(\mathbb{P}^3, \mathcal{O}_{\mathbb{P}^3}(1))$ and $r_0 \geq \cdots \geq r_3 = 0$. Let L be the line defined by $X_2 = X_3 = 0$. Let $C_1 \cap (X_3 = 0) = \sum_{i=1}^n a_iq_i$ where $a_i \geq 1$, $\sum a_i = 5$, and $q_i \neq q_j$ for $i \neq j$. Then $e_F(C_1) = \sum_i e_F(C_1)_{q_i}$.

If $r_1 = r_2 = r_3 = 0$, $e_F(C) = e_F(C_1)_p + e_F(C_2)_p \leq 2r_0 < 3r_0 = 3\sum r_i$ where $p = (1, 0, 0, 0)$. If $r_0 = r_1 = r_2 = r$, then $e_F(C) = e_F(C_1) + e_F(C_2) = e_F(C_1)_p + e_F(C_2)p \leq 5r + 2r < 9r = \sum r_i$. Hence we may exclude these two cases.

Case 1. $C_2 = L$:

By Lemma 3.8, $e_F(C_2) = r_0 + r_1$.

We may assume that C_1 and C_2 meet at q_i for $i = 1, 2, 3$.

Take $i \in \{1, 2, 3\}$. Since C_1 meets C_2 transversally, $v(X_2) = 1$ or $v(X_3) = 1$ where v is the natural valuation on $\mathcal{O}_{C_1,q_i}$. So, if $q_i \neq (1, 0, 0, 0)$ then $\mathcal{I}(C_1)_{q_i \times \{0\}} = (t^{r_1}, t^{r_2}s, s^{a_i})$, and if $q_i = (1, 0, 0, 0)$ then $\mathcal{I}(C_1)_{q_i \times \{0\}} = (t^{r_0}, t^{r_2}s, s^{a_i})$.

On the other hand, $e_F(C_1)_{q_i} \leq a_i r_2$ for $q_i \notin L$ by Lemma 3.3.

Case 1.1. $q_i \neq (1, 0, 0, 0)$ for all i:

Since $a_1 + a_2 + a_3 \leq 5$ and $a_i \geq 1$, we may assume $a_1 = 1$. Thus $e_F(C_1)_{q_1} = r_1$, $e_F(C_1)_{q_2} \leq r_1 + a_2 r_2$, and $e_F(C_1)_{q_3} \leq r_1 + a_3 r_2$. Hence

$$\begin{aligned} e_F(C) &= e_F(C_1) + e_F(C_2) = \sum e_F(C_1)_{q_i} + e_F(C_2) \\ &\leq \{r_1 + (r_1 + a_2 r_2) + (r_1 + a_3 r_2)\} + \sum_{i \neq 1,2,3} a_i r_2 + (r_0 + r_1) \\ &= r_0 + 4r_1 + 4r_2 < 3 \sum r_i. \end{aligned}$$

Case 1.2 $q_1 = (1, 0, 0, 0)$:

Suppose $a_1 = 1$. Then $e_F(C_1)_{q_1} = r_0$, $e_F(C_1)_{q_2} \leq r_1 + a_2 r_2$, and $e_F(C_1)_{q_3} \leq r_1 + a_3 r_2$. Therefore

$$\begin{aligned} e_F(C) &= e_F(C_1) + e_F(C_2) = \sum e_F(C_1)_{q_i} + e_F(C_2) \\ &\leq \{r_0 + (r_1 + a_2 r_2) + (r_1 + a_3 r_2)\} + \sum_{i \neq 1,2,3} a_i r_2 + (r_0 + r_1) \\ &= 2r_0 + 3r_1 + 4r_2 < 3 \sum r_i. \end{aligned}$$

Suppose $a_1 \geq 2$. Then we may assume $a_2 = 1$. Hence $e_F(C_1)_{q_1} \leq r_0 + a_1 r_2$, $e_F(C_1)_{q_2} \leq r_1$, and $e_F(C_1)_{q_3} \leq r_1 + a_3 r_2$. Therefore

$$\begin{aligned} e_F(C) &= e_F(C_1) + e_F(C_2) = \sum e_F(C_1)_{q_i} + e_F(C_2) \\ &\leq \{(r_0 + a_1 r_2) + r_1 + (r_1 + a_3 r_2)\} + \sum_{i \neq 1,2,3} a_i r_2 + (r_0 + r_1) \\ &= 2r_0 + 3r_1 + 4r_2 < 3 \sum r_i. \end{aligned}$$

Case 2. $C_2 \neq L$:

By Lemma 3.8 and 3.9, we have $e_F(C_2) \leq r_0 + r_2$.

Suppose there exists i such that $q_i \notin L$. Then $e_F(C_1) \leq r_0 + 4r_1 + r_2$ by Remark 3.4. Hence

$$e_F(C) = e_F(C_1) + e_F(C_2) \leq 2r_0 + 4r_1 + 2r_2 \leq 3 \sum r_i.$$

In the last inequality, the equality holds if and only if $r_2 = 0$ and $r_0 = r_1 = r$. In this case, $e_F(C_1) \leq 4r$ by Remark 3.4 and $e_F(C_2) \leq r$ by Lemma 3.9. Thus $e_F(C) \leq 5r < 6r = 3 \sum r_i$.

Suppose C_2 does not meet L. Then $e_F(C_2) = r_2$ by Lemma 3.9. Since $e_F(C_1) \leq r_0 + 5r_1$ by Remark 3.4, we have

$$e_F(C) = e_F(C_1) + e_F(C_2) \leq (r_0 + 5r_1) + r_2 \leq 3 \sum r_i.$$

In the last inequality, the equality holds if and only if $r_0 = r_1 = r$ and $r_2 = 0$. In this case, $e_F(C_1) \leq 5r$ and $e_F(C_2) = 0$. Thus $e_F(C) \leq 5r < 6r = 3\sum r_i$.

In all, we may assume $q_i \in L$ for all $i = 1,..,n$, and C_2 meets L.

Since C_1 meets C_2 transversely at 3 points and $C_2 \neq L$, we can see that C_2 is not contained in $(X_3 = 0)$. Hence $e_F(C_2) \leq r_0$ by Lemma 3.9.

Let H be the hyperplane which is determined by C_2 and L. Since C_1 meets C_2 transversely at three points and $q_i \in L$ for all $i = 1, ..., n$, we have

$$\sum_{i=1}^{n} \min\{v(X_2), v(X_3) | v \text{ the natural valuation on } \mathcal{O}_{C_1,q_i}\} \leq 3.$$

In particular, $n \leq 3$. In fact, if not, the number of points in $C_1 \cap H$ is greater than or equal to 6. This contradicts the degree assumption. Hence we have the following three subcases.

Case 2.1. $n = 3$:

Let $C_1 \cap (X_3 = 0) = a_1q_1 + a_2q_2 + a_3q_3$ where $a_i > 0$ and $\sum a_i = 5$.

For each i, we have $v(X_2) = 1$ or $v(X_3) = 1$ where v is the natural valuation of $\mathcal{O}_{C_1,q_i}$. Hence, if $q_i \neq (1, 0, 0, 0)$ then $\mathcal{I}(C_1)_{q_i \times \{0\}} = (t^{r_1}, t^{r_2}s, s^{a_i})$, and if $q_i = (1, 0, 0, 0)$ then $\mathcal{I}(C_1)_{q_i \times \{0\}} = (t^{r_0}, t^{r_2}s, s^{a_i})$. Therefore

$$\begin{aligned} e_F(C) &= e_F(C_1) + e_F(C_2) \\ &\leq \{(r_0 + a_1r_2) + (r_1 + a_2r_2) + (r_1 + a_3r_2)\} + r_0 \\ &= 2r_0 + 2r_1 + 5r_2 < 3\sum r_i. \end{aligned}$$

Case 2.2. $n = 2$:

Let $C_1 \cap (X_3 = 0) = a_1q_1 + a_2q_2$ where $a_i > 0$ and $a_1 + a_2 = 5$.

We may assume $\min\{v(X_2), v(X_3) | v \text{ the natural valuation on } \mathcal{O}_{C_1,q_1}\} = k \leq 2$ and $\min\{v(X_2), v(X_3) | v \text{ the natural valuation on } \mathcal{O}_{C_1,q_2}\} = 1$.

Suppose $q_2 = (1, 0, 0, 0)$. Since $q_1 \neq (1, 0, 0, 0)$ and $q_1 \in L$, the valuation of X_1 of the natural valuation on $\mathcal{O}_{C_1,q_1}$ is 0 and thus $\mathcal{I}(C_1)_{q_1 \times \{0\}} = (t^{r_1}, t^{r_2}s^k, s^{a_1})$. On the other hand, $\mathcal{I}(C_1)_{q_2 \times \{0\}} = (t^{r_0}, t^{r_2}s, s^{a_2})$. Therefore

$$e_F(C_1) = e_F(C_1)_{q_1} + e_F(C_1)_{q_2} \leq (kr_1 + a_1r_2) + (r_0 + a_2r_2) = r_0 + kr_1 + 5r_2.$$

Hence $e_F(C) = e_F(C_1) + e_F(C_2) \leq 2r_0 + kr_1 + 5r_2 < 3\sum r_i$.

Assume $q_2 \neq (1, 0, 0, 0)$. Since $\mathcal{I}(C_1)_{q_1 \times \{0\}} > (t^{r_0}, t^{r_2}s^k, s^{a_1})$ and $\mathcal{I}(C_1)_{q_2 \times \{0\}} = (t^{r_1}, t^{r_2}s, s^{a_2})$, we have

$$e_F(C_1) \leq (kr_0 + a_1r_2) + (r_1 + a_2r_2) = kr_0 + r_1 + 5r_2.$$

Thus $e_F(C) = e_F(C_1) + e_F(C_2) \leq (k+1)r_0 + r_1 + 5r_2 \leq 3\sum r_i$. In the last inequality, the equality holds if and only if $k = 2$, $r_1 = r_2 = 0$. Now, let $k = 2$, $r_1 = r_2 = 0$. If $q_1 \neq (1, 0, 0, 0)$, $e_F(C_1) = 0$. If $q_1 = (1, 0, 0, 0)$, since $\mathcal{I}(C_1)_{q_1 \times \{0\}} = (t^{r_0}, s)$, we have $e_F(C_1) = r_0$. Therefore, in any case, $e_F(C) = e_F(C_1) + e_F(C_2) \leq r_0 + r_0 \leq \sum r_i$.

Case 2.3. $n = 1$:

Let $C_1 \cap (X_3 = 0) = 5q_1$.

Then $v(X_2) \leq 3$ where v is the natural valuation on $\mathcal{O}_{C_1,q_1}$. Thus $\mathcal{I}(C_1)_{q_1 \times \{0\}} > (t^{r_0}, t^{r_2}s^3, s^5)$ and hence $e_F(C_1) = e_F(C_1)_{q_1} \leq 3r_0 + 5r_2$. Therefore

$$e_F(C) = e_F(C_1) + e_F(C_2) \leq (3r_0 + 5r_2) + r_0 = 4r_0 + 5r_2.$$

Since $e_F(C_1) \leq r_0 + 5r_1$, we have

$$e_F(C) = e_F(C_1) + e_F(C_2) \leq (r_0 + 5r_1) + r_0 = 2r_0 + 5r_1.$$

Suppose $4r_0 + 5r_2 \geq 3\sum r_i$ and $2r_0 + 5r_1 \geq 3\sum r_i$. Then $r_0 + 2r_2 \geq 3r_1$ and $2r_1 \geq r_0+3r_2$. Hence $2r_0+4r_2 \geq 6r_1 \geq 3r_0+9r_2$. Therefore $r_0+5r_2 \leq 0$. We have a contradiction. Hence $e_F(C) \leq 4r_0+5r_2 < 3\sum r_i$ or $e_F(C) \leq 2r_0+5r_1 < 3\sum r_i$. $\square$

Proposition 3.22. *Let C be a curve of* Type3*. Then C is Chow stable.*

Proof. Let $C_1 \cap C_2 = \{p_1, p_2, p_3, p_4\}$. As a subvariety of $\mathbb{P}^3$ embedded by $|\omega_C|$, $\deg C_1 = 4$ and $\deg C_2 = 2$. Also C_1 is nondegnenerate and C_2 is contained in a hyperplane which is denoted by H. Since $C_2 \subset H$ and $\deg C_1 = 4$, we can see that $C_1 \cap H = p_1 + p_2 + p_3 + p_4$.

Let F be the weighted flag determined by coordinates X_0,...,X_3 and $r_0 \geq \cdots \geq r_3 = 0$. Let $L := (X_2 = X_3 = 0)$.

Case 1. $H \neq (X_3 = 0)$:

Suppose $L \subset H$. Since $C_1 \cap H = p_1 + p_2 + p_3 + p_4$, for a point $p \in C_1$ which lies on L, we have $v(X_2) = 1$ or $v(X_3) = 1$ where v is the natural valuation on $\mathcal{O}_{C_1,p}$. Since C_2 is irreducible, the number of points in $\{p_1, p_2, p_3, p_4\}$ lying on L is less than or equal to 2. Since $C_1 \cap (X_3 = 0) \cap L \subset C_1 \cap H$, there exists at most two distinct points in $C_1 \cap (X_3 = 0)$ lying on L. Let p be a point in C_1 which lies on L. If $p = (1, 0, 0, 0)$ then $\mathcal{I}(C_1)_{p\times\{0\}} > (t^{r_0}, t^{r_2}s, t^{v_3})$, and if $p \neq (1, 0, 0, 0)$ then $\mathcal{I}(C_1)_{p\times\{0\}} > (t^{r_1}, t^{r_2}s, t^{v_3})$. Hence

$$e_F(C_1) = \sum_{p\in L} e_F(C_1)_p + \sum_{p\notin L} e_F(C_1)_p \leq r_0 + r_1 + 4r_2.$$

Therefore

$$\begin{aligned} e_F(C) = e_F(C_1) + e_F(C_2) &\leq (r_0 + r_1 + 4r_2) + (r_0 + 2r_1) \\ &= 2r_0 + 3r_1 + 4r_2 \leq 3\sum r_i. \end{aligned}$$

In the last inequality, the equality holds if and only if $r_0 = r_1 = r_2 = r$. In this case, $e_F(C) = e_F(C_1) + e_F(C_2) = 4r + 2r < 9r = 3\sum r_i$.

In all, we may assume $L \not\subseteq H$.

Suppose $C_2 \cap (X_3 = 0) = p + q$ where $p \neq q$. Since C_2 is contained in H, at least one of p, q does not lie on L, and thus $e_F(C_2) \leq r_0 + r_2$ by Remark 3.4.

Assume $C_2 \cap (X_3 = 0) = 2p$. Since $C_2 \subset H$ and $L \not\subseteq H$, we get $v(X_2) = 1$ where v is the natural valuation of $\mathcal{O}_{C_2,p}$. Thus $\mathcal{I}(C_2)_{p\times\{0\}} > (t^{r_0}, t^{r_2}s, s^2)$ and hence $e_F(C_2) \leq r_0 + 2r_2$.

Therefore, in any case,

$$e_F(C) = e_F(C_1) + e_F(C_2) \leq (r_0 + 4r_1) + (r_0 + 2r_2) = 2r_0 + 4r_1 + 2r_2 \leq 3\sum r_i.$$

In the last inequality, the equality holds if and only if $r_0 = r_1 = r$ and $r_2 = 0$. In this case, $e_F(C) = e_F(C_1) + e_F(C_2) = 4r + r = 5r < 6r = 3\sum r_i$.

Case 2. $H = (X_3 = 0)$:

Clearly $C_1 \cap (X_3 = 0) = p_1 + p_2 + p_3 + p_4$. Since C_2 is irreducible and $\deg C_2 = 2$, any three points in $\{p_1, p_2, p_3, p_4\}$ does not lie on L. Hence $e_F(C_1) \leq r_0 + r_1 + 2r_2$.

Let F' be the weighted filtration of $H_1 = \mathbb{P}^2$ with weights $r'_0 = r_0 - r_2, r'_1 = r_1 - r_2, r'_2 = r_2 - r_2 = 0$ and coordinate system X_0, X_1, X_2 which is induced from that of F. Then, by Lemma 3.10,

$$e_F(C_2) - \frac{4}{3}(r_0 + r_1 + r_2) = e_{F'}(C_2) - \frac{4}{3}(r'_0 + r'_1 + r'_2).$$

Hence $e_F(C_2) = e_{F'}(C_2) + 4r_2 \leq r'_0 + 2r'_1 + 4r_2 = r_0 + 2r_1 + r_2$ where the first inequality comes from Remark 3.6 . Therefore

$$\begin{aligned} e_F(C) = e_F(C_1) + e_F(C_2) &\leq (r_0 + r_1 + 2r_2) + (r_0 + 2r_1 + 2r_2) \\ &= 2r_0 + 3r_1 + 3r_2 < 3\sum r_i. \end{aligned}$$

□

Let C be a curve of Type4. Then C is canonically embedded in $\mathbb{P}^3$ and, as a subvariety of $\mathbb{P}^3$, $\deg C_1 = \deg C_2 = 3$ and C_i is nondegnenerate for $i = 1, 2$. In this case, we have the following Proposition.

Proposition 3.23. *Let C be a curve of* Type4. *Then C is Chow stable.*

Proof. Let F be the weighted flag determined by X_0,...,X_3 and $r_0 \geq \cdots \geq r_3 = 0$. Let $L := (X_2 = X_3 = 0)$.

If $r_1 = r_2 = r_3 = 0$, $e_F(C) = e_F(C_1)_p + e_F(C_2)_p \leq 2r_0 < 3r_0 = 3\sum r_i$ where $p = (1, 0, 0, 0)$. If $r_0 = r_1 = r_2 = r$, then $e_F(C) \leq 3r + 3r = 6r < 9r = 3\sum r_i$. Thus we may exclude these two cases.

Suppose, for each $i = 1, 2$, there exists a point in $C_i \cap (X_3 = 0)$ which does not lie on L. Then

$$e_F(C) = e_F(C_1) + e_F(C_2) \leq (r_0 + 2r_1 + r_2) + (r_0 + 2r_1 + r_2) \leq 3\sum r_i.$$

In the last inequality, the equality holds if and only if $r_0 = r_1 = r$ and $r_2 = 0$. In this case, $e_F(C) = e_F(C_1) + e_F(C_2) \leq 2r + 2r = 4r < 6r = 3\sum r_i$.

Thus we may assume that every point in $C_1 \cap (X_3 = 0)$ lies on L.

Since C_1 is nondegenerate, $C_1 \cap (X_3 = 0) = 2p + q$ for $p \neq q$, or $C_1 \cap (X_3 = 0) = 3p$. Let us consider these two cases.

Suppose $C_1 \cap (X_3 = 0) = 2p + q$ where $p \neq q$. Since $\deg C_1$=3 , p and q lie on L, and C_1 is nondegenerate, we can see that $v(X_2) = 1$ where v is the natural valuation on $\mathcal{O}_{C_1,p}$. If $p = (1, 0, 0, 0)$ then $\mathcal{I}(C_1)_{p\times\{0\}} = (t^{r_0}, t^{r_2}s, s^2)$ and if $p \neq (1, 0, 0, 0)$ then $\mathcal{I}(C_1)_{p\times\{0\}} = (t^{r_1}, t^{r_2}s, s^2)$. Hence

$$e_F(C_1) = e_F(C_1)_p + e_F(C_1)_q \leq (r_0 + 2r_2) + r_1 = (r_1 + 2r_2) + r_0 = r_0 + r_1 + 2r_2.$$

Suppose $C_1 \cap (X_3 = 0) = 3p$. If L is the tangent line of C_1 at p, then $\mathcal{I}(C_1)_{p\times\{0\}} > (t^{r_0}, t^{r_2}s^2, s^3)$ and hence

$$e_F(C_1) \leq 2r_0 + 3r_2.$$

If L is not the tangent line of C_1 at p, then $\mathcal{I}(C_1)_{p\times\{0\}} > (t^{r_0}, t^{r_2}s, s^3)$ and hence

$$e_F(C_1) \leq r_0 + 3r_2.$$

Suppose there exists a point in $C_2 \cap (X_3 = 0)$ which does not lie on L. Then $e_F(C_2) \leq r_0+2r_1+r_2$. Since $(r_0+r_1+2r_2)+(r_0+2r_1+r_2) = 2r_0+3r_1+3r_2 < 3\sum r_i$ and $(2r_0 + 3r_2) + (r_0 + 2r_1 + r_2) = 3r_0 + 2r_1 + 4r_2 < 3\sum r_i$, we get $e_F(C) = e_F(C_1) + e_F(C_2) < 3\sum r_i$.

Assume that every point in $C_2 \cap (X_3 = 0)$ lies on L. Then the same argument for C_1 also holds for C_2. Note that C_1 and C_2 can not have common tangent line at any point. Since $(r_0 + r_1 + 2r_2) + (r_0 + r_1 + 2r_2) = 2r_0 + 2r_1 + 4r_2 < 3\sum r_i$, $(r_0+r_1+2r_2)+(2r_0+3r_2) = 3r_0+r_1+4r_2 < 3\sum r_i$ and $(r_0+3r_1)+(r_0+3r_2) = r_0 + 3r_1 + 3r_2 < 3\sum r_i$, we can see that $e_F(C) = e_F(C_1) + e_F(C_2) < 3\sum r_i$. $\square$

In all, we have the following theorem.

Theorem 3.24. *All three connected stable curves of genus 4 with two smooth components except 3-pointed elliptic tails are Chow stable.*

For the definition of three connectedness, we refer to [10].

Acknowledgments

This work is a large part of the author's Ph.D. thesis submitted to Sogang University in 2007 written under Yongnam Lee. The author wishes to thank him for his guidance and patience. Also the author thanks Brendan Hassett for valuable comments. This work was supported by the Korea Science and Engineering Foundation (KOSEF) grant funded by the Korea government (MOST) (No. R01-2007-000-10948-0), and by the BK21 project of the Ministry of Education, Korea.
